Finding eigenvalues

If λ is an eigenvalue for A , then $A - \lambda I = 0$ has a non-trivial solution and is not invertible. This is equivalent to finding when the determinant of $A - \lambda I$ is equal to zero. In an upper and lower triangular matrix, the eigenvalues are the values along the diagonal.

$$\det(A - \lambda I) = 0$$

This determinant will give a polynomial of degree n . This is called the characteristic polynomial.

- The eigenvalues of A are solutions of the characteristic equation of A .
- The algebraic multiplicity of an eigenvalue λ is degree of the λ root in the characteristic equation.
- The geometric multiplicity of λ is the dimension of the λ -eigenspace.
- The geometric multiplicity is always less than or equal to the algebraic multiplicity.

Example 1

$$\begin{aligned} A &= \begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix} \\ \det(A - \lambda I) &= \det \begin{bmatrix} 1 - \lambda & 1 \\ 0 & 1 - \lambda \end{bmatrix} \\ &= (1 - \lambda)^2 \end{aligned}$$

$\lambda = 1$ is the only eigenvalue and has an algebraic multiplicity of 2.

$$\begin{aligned} \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix} u &= \begin{bmatrix} 0 \\ 0 \end{bmatrix} \\ u &= t \begin{bmatrix} 1 \\ 0 \end{bmatrix} \end{aligned}$$

The dimension of the 1-eigenspace has a dimension of 1, thus a geometric multiplicity of 1.

Example 2

Find the eigenvalues of the following matrix.

$$A = \begin{bmatrix} 1 & -7 & 3 & 4 \\ 0 & 2 & 1 & -1 \\ 0 & 0 & 6 & 3 \\ 0 & 0 & 0 & -1 \end{bmatrix}$$

$$A - \lambda I = \begin{bmatrix} 1 - \lambda & -7 & 3 & 4 \\ 0 & 2 - \lambda & 1 & -1 \\ 0 & 0 & 6 - \lambda & 3 \\ 0 & 0 & 0 & -1 - \lambda \end{bmatrix}$$

$$\det(A - \lambda I) = (1 - \lambda)(2 - \lambda)(6 - \lambda)(-1 - \lambda) = 0$$

$$\lambda = 1, 2, 6, -1$$
